RESEARCH ACTIVITIES

My research activities are focused on understanding and manipulating nanomechanical effects at interfaces and using that knowledge for the development of high-performance sensors, devices, and materials, for applications in health, environment, and energy. These interdisciplinary research efforts cover from basic research to design and development of complete systems. Multi-modal and multi-physics approaches are used for generating orthogonal data for high performance sensing. These approaches include molecular engineering of surfaces and interfaces, modulation of adsorbates with optical, thermal, and electrical/electrochemical modulation, etc. To address the challenge of delivery

electrical power to the sensors a new concept of transferring electrical power through a single wire has been developed. New concepts in energy conversion, storage, and transmission are pursued.

Significant Career Accomplishments:

- Developed new technique of tribotunnelling for energy harvesting (2017)
- Pioneered the development of single wire (single contact) electricity transmission concept (2010)
- Developed multi-physics sensor concepts of combining electrical, optical, and mechanical resonances (2000)
- Pioneered the development of a novel class of physical, chemical, and biological sensors based on adsorption-induced force (1991)
- Developed and patented micromechanical infrared detection, imaging technique including mechanical IR spectroscopy (1995)
